

SPECIFICATION

TITLE: EMERGENCY VEHICLE TRAFFIC SIGNAL PREEMPTION SYSTEM

This application is a Continuation-In-Part of Application Serial No. 10/642,435, filed August 15, 2003, and Application Serial No. 60/403,916 filed August 15, 2002. The invention described herein was made in the performance of work under a NASA contract and is subject to the provisions of Public Law 96-517 (U.S.C. 202) in which the Contractor has elected to retain title.

BACKGROUND OF THE INVENTION

1. Field of the Invention

This invention relates to systems for controlling vehicle traffic signals to allow safe passage of emergency vehicles and more particularly relates to a system for autonomously preempting traffic signals at an intersection that includes a vehicle transponder, a real-time intersection controller and monitor (with an intersection-based visual and/or audio alarm warning system), an operations display and control software, and a wide-area communications network.

2. Background Information

Present systems used to preempt traffic signals and clear intersections for emergency vehicles responding to a life-saving event often come with severe limitations. They rely on:

1 sound activation, optical activation, direct microwave
2 activation, and a combination of all the above. All of these
3 systems have severe operational limitations affected by
4 weather, line of sight, and critical range. These systems
5 often have further drawbacks requiring them to be activated by
6 the emergency vehicle operator or first responder (herein
7 referred to as "e-operator"). These systems also severely
8 disrupt the normal phasing patterns of a traffic controller's
9 nominal programming because these systems do not provide real-
10 time monitoring of intersection phases or timing.

11 Emergency vehicles currently rely on vehicle horn, sirens,
12 and flashing lights to prevent accidental collisions with
13 pedestrians or other vehicles at intersections. E-operators
14 must focus all their attention on driving the vehicles. Other
15 preemption systems fail to provide visual or audio feedback
16 systems (to either motorists or e-operators) that are
17 physically located in the intersection (herein referred to as
18 "intersection-based warnings"). Such preemption systems
19 compromise motorist and e-operator safety, as there is no
20 awareness of a traffic-light preemption event (referred herein
21 as "silent preemption"). Additionally, these systems fail to
22 provide real-time feedback to e-operators through warning
23 devices inside their vehicles (herein referred to as "vehicle-
24 based warnings"). These factors have the effect that e-

1 operators do not get the feedback required and soon stop using
2 the system.

3 An intersection-based preemption system that provides
4 feedback and is activated autonomously by an approaching
5 emergency vehicle is needed. Such a system overcomes some of
6 the drawbacks of available systems. Intersection-based visual
7 warnings are proven effective for motorists, and are also
8 critically important to e-operators when multiple emergency
9 vehicles are approaching the same intersections (referred
10 herein as "conflict detection"). These displays are directly
11 in their field-of-vision and e-operators are immediately aware
12 of potential conflicts. Human factors studies often refer to
13 such indicators as "real-world". Intersection-based warnings
14 combined with autonomous activation removes the distraction by
15 keeping drivers' eyes on the road.

16 A system is needed that takes special consideration of
17 pedestrians. Visual intersection-based warnings may fail to
18 get the attention of pedestrians standing near an intersection.
19 For this reason, audible alerts in addition to visual may be
20 the most effective (and rapid) warning system of the approach
21 of emergency vehicles. There is also the difficulty that
22 pedestrians may often be in harms way if they fail to hear an
23 approaching emergency vehicle. Although vehicle sirens are
24 especially loud, many circumstances can lead to dangerous

1 situations and potential injury. For instance, an especially
2 long crosswalk may take up to 20 seconds to cross. In that
3 time, an emergency vehicle may be heard, perhaps stranding the
4 pedestrian in the middle of a crosswalk. Likewise, in
5 extremely busy metropolitan intersections, ambient noise in the
6 building occlusions may prevent warning of the emergency
7 vehicle until just seconds before the vehicle arrived at an
8 intersection. A system is needed that disables normal
9 pedestrian clearance at intersections long before actual
10 preemption has been triggered (herein referred to as
11 "pedestrian-inhibit"). This system would greatly enhance the
12 safety of emergency vehicle preemption by preventing
13 pedestrians from entering an intersection long before a vehicle
14 arrives (or can be seen or heard).

15 Existing preemption systems provide little or no
16 visibility, configuration control, or remote interaction with
17 their operation or function. A system is needed that provides
18 real-time feedback, monitoring, logging, and control of vehicle
19 and intersection preemption-related data. This data would be
20 displayed at both mobile stations and central operation
21 center(s). Additionally, a system is needed that provides
22 secure, robust transfer of data to/from intersections,
23 vehicles, and operation center(s) using either wireless or LAN
24 architectures. All of these functions enable logistical

1 commanders and traffic management authorities to coordinate,
2 configure, and monitor activity in the overall preemption
3 network.

4 It is one object of the present invention to provide an
5 emergency vehicle traffic signal preemption system that is
6 fully autonomous and not dependent on the intersection being in
7 visual range.

8 Still another object of the present invention is to
9 provide an emergency vehicle traffic signal preemption system
10 that includes a real-time monitor of intersection phase to
11 optimize triggers and timing for both preempt and pedestrian-
12 inhibit functions. This includes minimizing disruption of
13 normal traffic controller behavior and sequencing.

14 Still another object of the present invention is to
15 provide an emergency vehicle traffic preemption system that
16 includes visual displays in the intersections (and interfaces
17 to such displays) indicating direction and location of
18 approaching emergency vehicle(s).

19 Still another object of the present invention is to
20 provide an emergency vehicle traffic signal preemption system
21 that provides conflict detection (between emergency vehicles
22 and e-operators) and alerts other emergency vehicles in the
23 area. This conflict detection is provided in two forms:
24 intersection-based warnings and vehicle-based warnings.

1 Still another object of the present invention is to
2 provide an emergency vehicle traffic signal preemption system
3 that includes a pedestrian audio warning signal to supplement
4 the intersection-based visual display and the audio signals
5 from emergency vehicles.

6 Yet another object of the present invention is to provide
7 an emergency vehicle preemption system having an autonomous
8 emergency vehicle transponder including an on-board diagnostic
9 (OBD) interface, a real-time navigation interface and position
10 estimation module, and a communications monitor and control
11 interface.

12 Still another object of the present invention is to
13 provide an emergency vehicle traffic signal preemption system
14 that allows real-time remote access, monitoring, and tracking
15 of the entire preemption system via secure wide-area networks
16 (wireless and LAN). This includes access to the operations
17 display and control software (herein referred to as "operations
18 software") from management centers (TMC, 911-call center,
19 etc.), mobile commanders, as well as individual emergency
20 responder vehicles.

21 BRIEF DESCRIPTION OF THE INVENTION

22 The purpose of the present invention is to provide an
23 improved emergency vehicle traffic signal preemption system
24 including autonomous operation, real-time phase monitoring and

1 visual/audio signals to alert motorists and pedestrians of the
2 approach of emergency vehicles.

3 The system is fully autonomous and is not affected by
4 range, weather, or line of sight. It provides real-time
5 monitoring of the intersection phases to optimize intersection
6 timing and provide the visual display to alert motorist of
7 oncoming emergency vehicle and the direction it is coming from.
8 This system is an improvement for use with the system disclosed
9 and described in U.S. Patent No. 4,704,610 of Smith et al
10 issued November 3, 1987 and incorporated herein by reference.
11 The system also provides an added feature of conflict
12 indication inside the emergency vehicle operator, indicating
13 that another emergency vehicle is responding and is approaching
14 the same intersection, indicating which vehicle has the
15 preemption and right of way.

16 This system is unique in that it is fully autonomous and
17 not dependent on the intersection being in visual range. It
18 provides conflict detection and alerts other emergency vehicle
19 operators in the area, has the ability to interrupt pedestrian
20 access, stops preemption when an emergency vehicle stops, and
21 provides interface to and control of the system disclosed and
22 described in the above-identified patent.

23 The improved emergency vehicle traffic signal preemption
24 system consists of three major subsystems. An intersection

1 monitor and control, an emergency vehicle transponder and its
2 interfaces, and a wide area communications network and its
3 associated proprietary control program software. The emergency
4 vehicle intersection preemption design connects intersections
5 and vehicles over a two-way wide area wireless communications
6 network. This network is synchronized via Global Positioning
7 System (GPS) timing signals. The system is also capable of
8 using existing traffic management LAN networks to relay data to
9 operations center(s).

10 When an e-operator receives an emergency response request,
11 the vehicle is placed in a priority-code (i.e. Code-3) mode
12 with lights and sirens operating. The vehicle emergency state
13 is read via an emergency-code vehicle interface. At the same
14 moment, the vehicle preemption transponder reads the vehicle
15 on-board diagnostics (OBD) data and determines speed and
16 acceleration, and gathers navigation data from one of several
17 navigation systems. This data is collected by an on-board
18 microprocessor that processes this information and predicts
19 heading and position. Estimation techniques include (but are
20 not limited to) dead reckoning and position hysteresis -
21 historical dependence - and are dependent on the sensor data
22 quality. This information is then formatted, the vehicle
23 identification (ID) and absolute time added, and the data is
24 then transmitted to various both intersections and vehicles

1 within the design area of coverage. The data is also
2 immediately forwarded along the network to subscribing mobile
3 and fixed operations center(s).

4 Intersection processors receive the data, identify the
5 vehicle's estimate-time-of-arrival (ETA), and compare it with
6 other vehicles possibly approaching their locations. It then
7 determines which vehicle obtains highest priority (depending on
8 location history, priority-type of vehicle, and other factors).
9 The processor sends notification to all approaching emergency
10 vehicles, warns of any potential conflict, and notifies the
11 local e-operators which vehicle has the right of way.

12 Simultaneously the processor collects real-time
13 intersection phasing and timing information and calculates when
14 preemption should start based on the vehicle(s) ETA. The
15 system includes the real-time monitoring of analog, digital,
16 and stand-alone (disabled monitoring) controllers. This
17 monitoring optimizes preempt behavior and provides a closed-
18 loop verification that preempt commands are executed by the
19 intersection controller.

20 It also calculates when to trigger the pedestrian-inhibit
21 function to prevent clearance for crossing access. When
22 preemption starts, intersection-based warning displays are sent
23 coded commands via a wireless or hard-line connection to light
24 the proper icons. For each direction, the displays show all

1 preempting emergency vehicles' direction and location, and
2 light the appropriate emergency vehicle message (i.e. "Warning
3 Emergency Vehicle"). All this takes place in real time, in a
4 manner appropriate to insure an intersection is preempted early
5 enough for safe and clear access, and in such a way as to
6 minimized speed reduction for the emergency vehicles.

7 The system disclosed herein provides a number of
8 improvements of the above-identified patent. It is an
9 autonomous system that does not need involvement of emergency
10 vehicle operator. It also includes expanded system
11 capabilities using emergency vehicle on-board diagnostics
12 (OBD), monitoring multiple emergency vehicles approaching the
13 same intersection using Global Positioning System (GPS), and
14 speed and heading information for multiple emergency vehicles
15 to determine the right of way. An intersection status is
16 transmitted to emergency vehicle dashboards indicating when the
17 intersection is safe to traverse. A dashboard display
18 indicates to the vehicle operator the status of an
19 intersection. The system is also capable of providing dynamic
20 and customized displays via an interface to the vehicle-based
21 PC (personal computer) systems. This interface provides
22 detailed, real-time positioning and status of all neighboring
23 emergency vehicles and intersections. It allows e-operators to
24 view maps with active vehicles and also allows for enhanced

1 conflict detection notification. The system also includes a
2 wide area wireless RF communication links between emergency
3 vehicles and intersections. This system is reliable and
4 unaffected by weather, rain, or lack of line of sight.

5 Simultaneous to preemption triggers, pedestrian audio
6 alerts are activated when emergency vehicles are approaching an
7 intersection. These are important because often visual signs
8 at an intersection may not be clearly visible to a pedestrian.
9 Beepers, bells, sirens, or even spoken instructions at high
10 volume can be used.

11 Several types of emergency vehicle location and navigation
12 information retrieval are possible. Among these are Global
13 Positioning Systems (GPS), dead reckoning, beacon
14 triangulation, tags, traffic loop, RDIF, etc. Each vehicle has
15 an identification (ID) tag that allows transmission to the
16 appropriate vehicle that it has the right-of-way to a preempted
17 intersection.

18 The improvements to the existing system in the above-
19 identified patent are to enhance the performance but the
20 purpose of the system remains the same. That is, to alert and
21 stop vehicles and pedestrians from using an intersection and to
22 allow an emergency vehicle to pass safely. Some prior warning
23 is necessary to allow clearing the intersection. The previous
24 implementation uses a one-way infrared link to transmit

1 approach and departure information of emergency vehicle to the
2 intersection which is equipped with four emergency vehicle
3 status display panels mounted next to the usual traffic lights
4 at each intersection.

5 The system transmits a signal causing all traffic lights
6 at an intersection to switch to "red" thus stopping all traffic
7 in all directions. In addition, the display panels flash a
8 relatively large "emergency vehicle" therein with a graphic
9 display indicating the lane and direction of traffic taken by
10 an emergency vehicle. The range of the infrared transmitter
11 can be as much as 1,000 feet allowing sufficient time to clear
12 the intersection. The new improved system utilizes a wide area
13 wireless RF two-way communication link between emergency
14 vehicles and intersections. This method is more reliable and
15 not affected by weather, lack of line of sight, range
16 limitation or obstructions.

17 Another advantage of the two-way wireless RF
18 communications link between the intersections and emergency
19 vehicles is the ability to display much more useful data in the
20 vehicles helping the vehicle operator maneuver his vehicle most
21 efficiently and safely. This data includes (but is not limited
22 to) emergency-code levels, vehicle acceleration, vehicle type,
23 and vehicle health. This method also enables feedback
24 communication to be sent from the intersections to the

1 vehicles, providing vehicle-based warnings (or confirmation) of
2 system activity. Intersection "green" status shows when an
3 intersection has been preempted and priority is given to the
4 receiving vehicle, allowing safe passage. If more than one
5 emergency vehicle approaches an intersection, the system
6 determines which vehicle should have the right of way depending
7 on location information (GPS, traffic loop, beacon, etc.),
8 direction and speed sent to the intersection control. A
9 proprietary control program determines the right of way and
10 sends the result to emergency vehicles. The encrypted data
11 package transmitted over transceivers is tagged with the
12 vehicle ID and time to insure proper and certified utilization.

13 Another improvement to the system is an audio warning
14 system intended to alert pedestrians that an intersection has
15 been preempted and must be kept clear. One desirable
16 implementation would utilize loudspeakers mounted near the four
17 corners of the intersection where pedestrians normally gather
18 to cross. A spoken message, such as "warning, emergency
19 vehicle approaching, do not walk", may be most preferred but
20 any audible signal such as a wailing sound, a siren, or any
21 other familiar emergency sound may be utilized.

22 Another goal of the improved system is creation of an
23 autonomous system that is activated by reception of a priority-
24 code (i.e. Code-3) status or alarm. The operator of the

1 emergency vehicle can concentrate on his primary duty which is
2 to arrive at the sight of the emergency safely in the shortest
3 time possible without worrying about the activation of the
4 system. A priority-code starts the process of communication
5 between an intersection that is being approached and the
6 emergency vehicle and the system performs the functions
7 described above. Also, both vehicle-based warnings and
8 intersection-based warnings provide positive feedback that an
9 e-operator has secured an intersection. This directly
10 translates into a reduction of emergency workers' stress
11 levels.

12 The information available from the emergency vehicle and
13 intersection controllers may be transmitted to a central
14 location such as a dispatch center or traffic control center to
15 display the status of multiplicity of intersections and
16 emergency vehicles. Such information being displayed on a
17 status board can be invaluable in managing emergency situations
18 (especially large-scale incidents) in a more sufficient manner
19 because it makes available information on a real-time basis for
20 the officials in charge. Commands and configuration
21 information can also be sent back to intersections and vehicles
22 to instantly meet changing needs or requirements. These
23 instructions can include the creation of large emergency
24 corridors (herein referred to as an "e-corridor") whereby a

1 series of sequential intersections are preempted in the same
2 direction.

3 The above and other objects, advantages, and novel
4 features of the invention will be more fully understood from
5 the following detailed description and the accompanying
6 drawings, in which:

7 BRIEF DESCRIPTION OF THE DRAWINGS

7 DETAILED DESCRIPTION OF THE INVENTION

8 The three major subsystems in the emergency vehicle
9 traffic signal preemption system are shown in Figure 5: the
10 vehicle transponder 200, the intersection hardware 230, and the
11 communications and operations network 260.

12 The vehicle transponder 200 is composed of three main
13 components. First, the vehicle computer interface module 205
14 includes the on-board diagnostics circuit and the emergency
15 priority code interface. Second, the navigation predict module
16 210 uses navigation sensors such as GPS and INU (inertial NAV
17 unit) sensors to generate both absolute and estimated dead
18 reckoning position reports. Third, the transponder control
19 module 215 provides an interface to the e-operator via LEDs, PC
20 display, or PDA device.

21 The intersection hardware 230 is composed of three main
22 components. First, the intersection monitor module 235
23 provides real-time reading and logging of controller signal and
24 pedestrian phasing and timing. Second, the intersection

1 control module 240 performs ETA calculations using vehicle
2 positions and local known mapping topology (commonly known as
3 map-matching). This module also tracks and logs vehicles,
4 actuates and verifies preempt signals, manages communications
5 between other networked units, and manages remotely-generated
6 intersection configuration commands. Third, the warning alerts
7 control module 245 actuates intersection-based visual and/or
8 audio warnings. This module also ensures that warning alerts
9 follow specific rules and timing parameters that govern the
10 sequencing of warning signs with traffic lights.

11 The communications and operations network 260 is composed
12 of three main components. First, the slave (end-unit)
13 transceivers in vehicles and intersections 275 relay the core
14 preemption status and configuration data to the backbone
15 network. Second, the backbone wireless or LAN network 270 is a
16 hybrid wide-area network designed to route data between mobile
17 wireless vehicles, hard-lined and isolated wireless
18 intersections, and the central operation center(s). Third, the
19 operations software 265 provides for display of all real-time
20 data generated by the intersections and vehicles including
21 positions/speed, phasing, preemption-status, vehicle
22 diagnostics, logged information, configuration data, and many
23 other data parameters. This display/control software 265 can
24 be mobilized for use in any management center, staging area, or

1 even an entire fleet of emergency vehicles.

2 The functional details of the major subsystems in the
3 emergency vehicle traffic signal preemption system are
4 illustrated in the block diagrams of Figure 1, Figure 2, and
5 Figure 13. Figure 1 illustrates the functional details of the
6 system at each intersection, Figure 2 illustrates the functions
7 of the system installed in an emergency vehicle, and Figure 13
8 illustrates the topology and display/control software used for
9 the communications and operations network.

10 Traffic light control system 100 at an intersection
11 includes traffic light controller 20 (housed in cabinet 500)
12 that generates the appropriate sequence of on-time and off-time
13 for the various traffic lights that controls vehicular and
14 pedestrian traffic at an intersection. Traffic light
15 controller 20 also has the capability to be forced by external
16 signals into a mode that activates "green" lights in a
17 specified direction and "red" lights in all other directions,
18 allowing safe passage for emergency vehicles from the "green"
19 direction. Controller 20 is preferably a micro-processing
20 circuit driving isolated lamp drivers but discrete designs are
21 also feasible. Some intersections may be more complicated,
22 controlling turn lanes with arrow lights, but the basic
23 principles remain the same.

24 An example of an intersection being controlled by the

1 system and functions disclosed and describe herein is shown in
2 Figure 1 of U.S. Patent No. 4,704,610 referred to hereinabove
3 and incorporated herein by reference. This figure shows the
4 signage and approach of emergency vehicles being controlled.
5 The only feature missing is the pedestrian control signs at
6 each corner which are an added feature of the invention
7 disclosed and described herein.

8 Traffic light controller 20 generates signals to control
9 pedestrian lights 22a, 22b, 22c, and 22d and also controls the
10 operation of traffic lights 24a, 24b, 24c, and 24d. An
11 intersection having traffic lights can be connected to a system
12 using the emergency vehicle preemption system by addition of
13 the functions described hereinafter without the need to rebuild
14 an existing installation.

15 The heart of the additional equipment is the intersection
16 control module, a microprocessor 515 (e.g., a ZWorld LP 3100
17 CPU) operated by proprietary control program software 35.
18 Controller 10 (housed in hardware module 510) receives
19 information from emergency vehicles that approach an
20 intersection via wireless RF transceiver 40 and antenna 41.
21 This information contains data about the predicted position,
22 heading, other navigation data of the emergency vehicle, and
23 its priority-code status 36 (i.e. Code-3, Code-2, or other)
24 thus notifying the intersection of its relative location.

1 Figure 9 illustrates the general functionality of the
2 intersection control program software and firmware 35 (see
3 Appendix B). The vehicle monitor software task 605 running on
4 the intersection CPU 515 tracks all local vehicles and
5 maintains a log of all activity. The task also sends conflict
6 detection warnings, when appropriate, to the vehicles.

7 The intersection control program 35 continually evaluates
8 its preemption rules as vehicle updates are received. Position
9 and priority parameters of each vehicle within range are
10 analyzed by the intersection preempt monitor software task 600.
11 The primary decision logic of this task is illustrated in
12 Figure 11. Appendix A provides detailed explanations of the
13 terms and parameters used in this figure and the description
14 below. The preempt monitor task uses map-matching techniques
15 to evaluate all vehicles against all eligible cross street
16 segments 700 to determine which vehicles are inbound or
17 outbound 730 from the intersection. The task assigns
18 preemption priority to that vehicle which is within critical
19 perimeter zones (pedestrian 705 and preempt 706), in high
20 priority priority-code 710, and is a valid vehicle type 720.
21 In order to optimize the preemption process, it compares the
22 minimum vehicle-ETA with both the intersection clearance time
23 (time-to-preempt) and a minimum complete-preemption time
24 (threshold) 715.

1 Figure 12 provides a visual illustration of the logic of
2 the intersection preempt monitor software task. The diagram
3 shows the actual positions (p_i) based in time along the actual
4 path 621 of the vehicle. For every actual position (p_i), there
5 is a same-time position report (e_i) along the estimated path 620
6 of the vehicle. For instance, p_1 623 and e_1 622 both occur at
7 same time t_1 . The diagram illustrates the estimate path 620
8 with valid position-lock (i.e. GPS occlusion), as well as
9 temporary loss of position-lock 624 when dead reckoning is used
10 to compensate. The diagram also illustrates the multiple uses
11 of proximity (perimeter) layers, with a pedestrian-inhibit
12 perimeter 625 ("max-PED-perimeter"), a preemption-allowed
13 perimeter 626 ("max-preempt-perimeter"), a critical distance
14 perimeter 627, and multiple critical distance street segments
15 628. Non-critical segments 636 are also shown (these street
16 segments require additional evaluation based on vehicle-ETA).
17 The exit window 631 displays an example exit distance range
18 where egress intersection-based warnings are allowed to be
19 activated (based on configurable minimum and maximum exit
20 distance criteria). Also, the evaluation of vehicle heading
21 compared against the road heading is shown as the direction-
22 error 622. The acceptable deviation of the estimated position
23 from the center-line of the street 630 is also shown.

24 Figure 12 also shows one of the more advanced preemption

1 techniques used on the intersection control program, the use of
2 "threshold-lag" 640, 641, and 642. "Threshold-lag" is defined
3 in Appendix-A. In simple terms it is percentage error factor
4 added to the threshold that gives the "benefit-of-the-doubt" to
5 any actively preempting vehicle. Initially (prior to
6 preemption), the threshold-lag factor 640 is zero percent (0%).
7 When the threshold is crossed, the threshold-lag becomes its
8 maximum value (i.e. 30%), and it is added to both the
9 threshold-time and the time-to-preempt factors for comparison
10 to vehicle-ETA. Once a vehicle has crossed the threshold, and
11 the threshold-lag has been expanded, the threshold-lag linearly
12 decreases back to zero percent (0%) over a small period (i.e.
13 10 seconds). This calculation is just one form of hysteresis
14 (historical dependence) techniques used in the invention.

15 Figures 6, 7 and 8 are schematics that show detailed
16 layouts of the intersection hardware components and, most
17 specifically, multiple configurations for real-time monitoring
18 of phasing/timing controller signals. The configuration in
19 Figure 7 provides for interfacing to digital BUS intersection
20 controllers 20b (such as NEMA TS1 controller models). The
21 configuration in Figure 8 provides for interfacing to analog-
22 based intersection controllers 20c (such as type 170 controller
23 models). On such analog systems, traffic lights signals are
24 monitored by a fail-safe, isolated, high impedance tap and

1 subsequent digital circuit processing. The monitor data is
2 available for remote monitoring via the wide area
3 communications and operations network. As shown in Figure 6,
4 the system is still compatible with controllers that disable
5 monitoring 20a or where monitoring is not desired.

6 Real-time monitor information is read and analyzed by the
7 intersection monitor software task 610. These calculated
8 values are forwarded to the preempt monitor 600, where these
9 intersection phasing values are integrated with real-time
10 vehicle information. The software attempts to optimize preempt
11 triggers with "time-to-preempt" calculations and "time-to-
12 pedestrian-inhibit" calculations, as compared to the ETA of all
13 approaching emergency vehicles. The goal is to provide minimal
14 disruption to the nominal controller behavior and to maximize
15 the throughput of emergency vehicles through the preemption
16 intersection network. Also, unlike other preemption systems,
17 beyond simply sending a preempt command (actuating a preempt
18 signal), the real-time monitor independently measures the state
19 of the controller-actuated traffic light signals. This
20 provides a critical closed-loop design: it assures that preempt
21 commands are actually executed.

22 Real-time status monitor 42 is unique because it verifies
23 the state of the traffic signals and sends the intersection
24 status (i.e. "intersection preempted", "conflict detected", or

1 "no preemption") to intersection control module 10. That is,
2 real-time status monitor receives (i.e., "reads") the output
3 from traffic light controller 20 and pedestrian lights 22a
4 through 22d and traffic lights 24a through 24d and transmits
5 that information to intersection control module 10.
6 Intersection control module 10 in turn relays that information
7 to emergency vehicles via wireless RF transceiver 40 and
8 antenna 41. Intersection control module 10 now sends signals
9 to emergency display panels 45a, 45b, 45c, and 45d to light and
10 flash large emergency signs with the proper icons at each
11 corner of an intersection showing the position of any
12 approaching emergency vehicle relative to the traffic lanes of
13 the intersection as shown and described in the above-identified
14 U.S. patent incorporated herein. The display panels 45a-45d
15 and proper icons used at each corner of an intersection are
16 shown in Figure 2 of the U.S. patent referenced hereinabove.
17 The signage is also illustrated in U.S. Design Patent No.
18 305,673, issued January 23, 1990, and also incorporated herein
19 by reference.

20 Also, the real-time status monitor 42 provides which is
21 transmitted via RF master transceiver (or LAN) 60 and antenna
22 61 to a central monitoring system such as a dispatcher's
23 office. Reciprocally, the intersection receives information on
24 the state of its neighboring intersections. This closed-loop

1 architecture allows various units in the network to accurately
2 predict future movement, log critical information, and notify
3 users of the system state.

4 The intersection control program 35 (specifically the
5 preempt monitor software task 600) uses map-matching techniques
6 to compare vehicle navigation and position estimates with the
7 approach paths (cross-streets stored locally as map vectors).
8 This way the intersection can determine if any vehicle is on an
9 inbound course towards the intersection by "snapping" it to the
10 closest street. As an example, one of the calculations is the
11 "critical distance" test. This evaluates whether an
12 approaching car has statistically committed itself to crossing
13 through the local intersection based on lack of turning
14 options. Because of the knowledge of the road map, the
15 intersection can preempt even when the "critical distance" is
16 not line-of-sight. As an additional example, in the event that
17 any vehicle comes with a "warning distance" of the intersection
18 (1000-ft commonly used), the control program 35 will actuate
19 pedestrian-inhibit functions. Pedestrian lights 22a through
20 22d are changed to prevent pedestrian traffic. Through a
21 combination of hysteresis-based (historical dependence)
22 algorithms and dynamic proximity "windows", the system is able
23 to optimally route emergency vehicles across the map grid. It
24 is also able to effectively mitigate lossy communications,

1 lossy navigation data, and other unpredictable delays in the
2 system.

3 Another improvement to the system is the provision of an
4 audio warning to pedestrians. Thus simultaneously with
5 controlling the lights and pedestrian flashing signals,
6 controller 10 generates an audio message to be delivered from
7 audio warning device 50 to speakers 51a through 51d.

8 As mentioned, the details of the software in the
9 intersection control program for implementing the functions of
10 the system are provided in Appendix B. Because the functions
11 controlled are described in great detail in the text, many
12 software solutions to implement the functions will be apparent
13 to those skilled in the art.

14 Emergency vehicle functions for the preemption system are
15 illustrated in the block diagram of Figure 2. A transponder
16 box 99 (and cables 98, 98a) are installed in each emergency
17 vehicle and provide the functions that facilitate communication
18 with preempt-able intersections, other emergency vehicles, and
19 also central monitoring stations such as a dispatching center.
20 Inputs and outputs to and from the emergency vehicle system are
21 handled by transponder control module 30 under the direction of
22 proprietary control program software 15. Vehicle parameters
23 are determined from several inputs provided to transponder
24 control module 30.

1 Vehicle position is available from GPS receiver 38 via
2 antenna 39. Several positioning inputs 96 are available from
3 ports in navigation input device 34. Optional alternative
4 inputs from ports and navigation input device 34 are INU
5 (inertial navigation and estimation unit 29) parameters
6 including accelerometers, gyroscopes, wheel-tachometers, and
7 heading indicators. Other inputs include ID tag tracking,
8 beacon triangulation, modified traffic loop detectors, and
9 others. Vehicle information such as speed and acceleration are
10 read in real-time from the vehicle computer 33 using the on-
11 board diagnostic (OBD) interface cable and connector 33a.
12 These signals are converted and verified by the OBD circuit
13 board 32 and the translated digital signals are input to
14 transponder control module 30 (embedded on a micro-controller
15 97).

16 The emergency vehicle transponder system communicates with
17 intersections via wireless RF transceiver 44 and antenna 45.
18 The vehicles and intersections software task 670 running on the
19 vehicle transponder handles incoming intersection preempt
20 alerts and vehicle position reports from nearby units. It
21 receives feedback verification and displays the information on-
22 board by activating one or more LEDs 56, 57, or 58 on the LED
23 display 54. If it receives a signal for safe passage through
24 an intersection, "green" LED 56 is illuminated. If another

1 high-priority emergency vehicle is concurrently trying to
2 preempt the same intersection, "yellow" LED 57 is illuminated.
3 Illumination of "red" LED 58 indicates that there is no
4 preemption at the intersection. LEDs 56 through 58 are driven
5 by "intersection preempted" logic circuit 55. Logic circuit 55
6 can also provide customized outputs to dynamic display devices
7 59, such as PC monitor displays (LCD's) and Personal Digital
8 Assistants (PDA's). Such devices are commonly used for law
9 enforcement applications within the vehicle. As mentioned, the
10 operations software shown in Figure 14 can be mobilized 80 and
11 run on any vehicle-based auxiliary hardware device with a
12 standard operating system. The vehicle interface software task
13 665 in the transponder control program allows advanced mapping
14 and alerting of active nearby intersections and vehicles.

15 Emergency vehicle status is available in real time via
16 master RF transceiver 64 and antenna 65 to a central monitoring
17 station. Thus the position of any vehicle as well as the
18 status at an intersection is always available at some centrally
19 located dispatch station.

20 As indicated previously, the software in control program
21 15 to implement the functions of the transponder described
22 above has many possible solutions. Thus the software provided
23 to control the operation of transponder control module 30 can
24 be designed and implemented by anyone skilled in the art given

1 the detailed explanation of the system and functions described
2 hereinabove. Also, as previously mentioned, Appendix B
3 provides detailed pseudo-code of a full-featured version of the
4 software for both the intersection and vehicle.

5 Figure 3 is a schematic block diagram of the transponder
6 system mounted in each vehicle. The transponder box 99 in the
7 vehicle receives power from car battery through the OBD
8 interface 33a. The transponder box 99 has a GPS receiver such
9 as that produced and manufactured by Garmin International
10 Incorporated. The transceiver can be a radio transceiver
11 produced and manufactured by Freewave Technologies of Boulder,
12 Colorado.

13 Figure 4 is a schematic diagram of the on-board diagnostic
14 (OBD) circuit for the vehicle-based electronics and
15 transponder. The on-board diagnostic circuit handles such
16 information as speed, acceleration, heading, ignition status,
17 etc. and generates the proper digital signals 96a for delivery
18 to transponder control module 30.

19 Figure 10 illustrates the general functionality of the
20 vehicle transponder control program software and firmware. The
21 program monitors and logs all in-range vehicles and
22 intersections and manages the data output to the operator
23 display. The core component of the transponder software is the
24 navigation prediction module software task 655. The task uses

1 position estimates by GPS and other absolute position inputs,
2 and combines data from accelerometers, gyroscopes, tachometers,
3 and heading indicators. This data is then integrated with
4 historical logs. This process, commonly known as dead
5 reckoning, uses accurate (yet possibly intermittent) position
6 reports integrated with time-based inertial navigation data to
7 generate enhanced position estimates. Position information is
8 forwarded to the transponder state and position monitor
9 software task 650. This task monitors vehicle state and
10 diagnostic inputs (such as Code-3) and generates position/state
11 reports to broadcast via the wireless network.

12 Figure 13 illustrates an example network topology for the
13 communications and operations network. Emergency vehicles 300
14 and 301 send navigation reports (i.e. GPS) and other
15 data/commands (via wireless connection) to/from intersections
16 and other local vehicles. Preemption-equipped intersections
17 305, 306, and 307 monitor navigation information from vehicles.
18 Intersections cooperatively and redundantly communicate with
19 each other 320 (via wireless or LAN) to enhance data accuracy
20 and ensure robust communications. Data is also passed along to
21 existing TMC (traffic management center) 330 using existing
22 city LAN communications network 325. If a LAN network is not
23 used, wireless systems can be substituted, such as through FMC
24 340 (fleet management center) systems. From there, FMC can

1 forward all data to/from vehicle and TMC.

2 Figure 14 is a block diagram of the operations software,
3 designed for use in central command centers, mobile command
4 stations, and in individual emergency vehicles. The diagram
5 illustrates the primary functional components of the software.
6 The primary components include algorithmic modules and visual
7 displays for: low-level data activity 405, priority alerts 410,
8 intersections' data 420, vehicles' data 430, and geographic
9 mapping 450. In Figures 15, 16, and 17, both data and displays
10 for these components are shown in an example preemption
11 scenario. This example demonstrates the real-time operations
12 monitoring of a conflict detection scenario, whereby two police
13 vehicles are approaching the same intersection in high priority
14 mode. Figure 15 shows incoming data 461 from vehicles and
15 intersections within the preemption operations communications
16 network 460. Textual status messages are provided on the data
17 status module display 405a. The data status module 405 also
18 maintains a historical record for all low-level communication
19 and data-flow activity. This module 405 relays all verified
20 and priority data messages 406 (i.e. position, preempt, and
21 conflict messages) to the alerts module 410. The alerts module
22 display 410a provides real-time visual notifications of current
23 high-priority events (i.e. active Code-3 vehicles and preempted
24 intersections) and enables rapid analysis of the current

1 preemption system status.

2 The alerts module 410 forwards all detailed data 411 to
3 the vehicles and intersections modules 420 and 430. The
4 intersection module display 420a shows real-time detailed
5 intersection data including the traffic light states 421a
6 (phasing) and pedestrian clearance states 421b. Also shown are
7 timing parameters 421c (for example, minimum ETA to
8 intersection for inbound direction) and display data (for
9 example, visual warning signs' states). The vehicle module
10 display 430a shows real-time detailed vehicle data including
11 estimated locations, car types, priority-states, navigation
12 data (such as heading), and other historical information.

13 All vehicles' and intersections' active data 411 is
14 integrated and overlaid on the mapping module display 450a.
15 The display is an adjustable city map with active units shown
16 as icons, such as vehicle units 431a, 431b and intersection
17 units 432. Visual high-priority alerts, such as conflict
18 detection warnings 433, are logistically overlaid on the map.

19 A secondary component of the operations software is used
20 for installation and real-time configuration of units 470 as
21 they are added to the preemption network. For intersections,
22 configuration commands 471 include the upload of street grid
23 databases, phase preemption information, and enter/exit
24 distance and timing. For vehicles, configuration commands 471

1 include ID tags, selection of vehicle type, and sensitivity
2 settings for navigation algorithms. Various test utilities
3 allow the installer to visually monitor the intersection and
4 approaching test vehicles. For instance, the system can be put
5 into the silent preempt mode (no warning signs), or can be
6 manually activated to preempt without a vehicle. The software
7 can communicate directly with a local intersection or vehicle,
8 or can use the local unit's transceiver to talk to the rest of
9 the network.

10 The operations software can be used to analyze (and
11 optimize) call response times and call response strategies
12 (routes, etc.). It can be used from any location within the
13 range of the network, and can also be integrated into existing
14 call-response centers. The software can also be used for
15 emergency logistics management (i.e. multiple car responses),
16 preventative warnings (i.e. conflict detection), and can also
17 be integrated into existing TMC incident management systems.
18 The system and displays can be accessed via the internet 480 as
19 well. Traffic technicians can use the system to monitor
20 phasing and optimize internal controller programming to match
21 desired preemption settings and behavior. The monitor software
22 is also able to identify potential problems or conflicts in the
23 network using intelligent "sniffer" software utilities. These
24 algorithms watch incoming data to make sure that data is

1 disseminated in real-time, that data is cohesive and error-
2 free, and that position/state reports are consistent. The
3 system also has the capacity to quickly and autonomously shut
4 off problem vehicle or intersection units. These utilities
5 allow the system to quickly identify anomalies and request
6 maintenance, thereby drastically reducing potentially
7 significant traffic problems.

8 Thus there has been disclosed improvements to an emergency
9 vehicle traffic signal preemption system. Improvements include
10 providing an autonomous system that is not dependent on
11 intersection being in visual range. The system provides
12 conflict detection and alerts emergency vehicle operators in
13 the area, and provides real-time monitoring of an intersection
14 phase. The real-time monitoring of intersections is indicated
15 by LEDs on a transponder or LCD display in the emergency
16 vehicle that show whether there is a conflict or the
17 intersection being approached is not preempted. The system
18 also includes the improvement of an audio alarm to alert
19 pedestrians who may not be aware of an approaching emergency
20 vehicle for various reasons or are at an angle where visible
21 signs are not clear.

22 This invention is not to be limited by the embodiment
23 shown in the drawings and described in the description which is
24 given by way of example and not of limitation, but only in

1 accordance with the scope of the appended claims.

24

1 calculation. It uses behavior or rules formed while collecting
2 previous time-based sequenced data to predict future behavior.
3 In the context of this preemption system, hysteresis is used to
4 address such observations as: "if an e-operator successfully
5 preempts a traffic light, the intersection program should be
6 very conservative and cautious before discontinuing the
7 preemption for that vehicle." This basic hysteresis approach
8 is illustrated in Figures 11 and 12. Advanced approaches use
9 tracking and prediction algorithms to more accurately assess
10 vehicle position, e-operator intent, and optimize intersection
11 controller behavior.

12 Operator-Configurable Values:

13 "Max-preempt-perimeter" is the maximum distance at which a
14 vehicle is allowed to preempt the local intersection. As
15 example, 3000-ft could be used.

16 "Street width" is the maximum deviation (distance) allowed
17 between the line-center of a street segment and a vehicle's
18 estimated position. If the calculated difference is less than
19 "street width", the vehicle is considered "on" a street
20 segment. As example, 50-ft could be used.

21 "Heading error" is the maximum deviation (angle) allowed
22 between the direction of a street segment and a vehicle's
23 estimate heading. If the difference between angles is less
24 than the "heading error", the vehicle is considered to be

1 moving "along" that street segment. As example, 15-degrees
2 could be used.

3 "Critical distance" is the distance within which a vehicle
4 is automatically marked as critical-inbound (if heading meets
5 criteria). As example, 200-ft could be used.

6 "Critical segment" is a boolean value that applies to all
7 street segments; if "yes" then any vehicle "on" that street
8 segment is automatically marked as critical-inbound (if heading
9 meets criteria).

10 "Max-PED-perimeter" is the distance within which
11 pedestrian-inhibit is enabled to prevent standard PED clearance
12 phases. As example, 2200-ft could be used.

13 "Min-exit-distance" is the minimum outbound distance past
14 which egress intersection-based warnings are allowed. As
15 example, 30-ft could be used.

16 "Max-exit-distance" is the maximum outbound distance up to
17 which egress intersection-based warnings are allowed. As
18 example, 100-ft could be used.

19 "Min-exit-speed" is the minimum speed above which outbound
20 intersection-based warnings are allowed. As example, 5-mph
21 could be used.

22 "Min-preempt-speed" is the minimum speed above which
23 inbound preemption and inbound intersection-based warnings are
24 allowed. As example, 10-mph could be used.

1 "Max-latency" is the maximum time between preempt-able
2 messages (see latency-counter description) from the same
3 vehicle before that vehicle is considered inactive. As
4 example, 6-secs could be used.

5 Software Derived/Calculated Values:

6 "Max-NAV-error" is the maximum estimated distance error
7 allowed for vehicle-ETA calculations, as determined by dead
8 reckoning algorithms and positioning device specifications.
9 Any error exceeding this factor will invalidate the associated
10 estimated vehicle position. As example, 150-ft could be used.

11 "Vehicle-ETA" is the minimum estimated ETA (estimated-
12 time-of-arrival) of a vehicle at an intersection, as calculated
13 using the real-time map distance between vehicle and
14 intersection, vehicle speed, vehicle acceleration (based on
15 historical averaging and vehicle type), street type, and
16 expected street conditions (i.e. time-of-day).

17 "Threshold-lag" is the minimum estimated time that the
18 complete-preemption state must remain steady prior to a
19 preempting vehicle's arrival at an intersection. This
20 calculation is based on the vehicle's speed. The purpose of
21 this factor is to minimize slowing of preempting vehicle. The
22 lag includes threshold-hysteresis (see below).

23 "Threshold-hysteresis" is a percentage time error included
24 in threshold-lag. When a vehicle preempts an intersection, the

1 threshold-hysteresis factor resets from 0% to a percentage of
2 the initial vehicle-ETA. For example, 30% could be the default
3 initial setting. Every second thereafter, this percentage is
4 reduced linearly, until 0%. This ensures that once a vehicle
5 is preempting, it is unlikely a temporary vehicle change will
6 disable preemption (i.e. slowing down).

7 "Time-to-preempt" is the minimum time to achieve complete
8 preemption at an intersection, estimated by the real-time
9 phasing monitor. One of the primary calculations to determine
10 a vehicle's preempt eligibility is if a vehicle's ETA is less
11 than the sum of the time-to-preempt and threshold-lag
12 parameters.

13 "Latency-counter" is the number of seconds since the last
14 "valid" preempt-able message was received from a given vehicle.
15 Some criteria that would cause the latency counter to increment
16 are: (a) a position report accuracy worse than Max-NAV-error,
17 (b) vehicle not "on" a street segment, (c) low or no vehicle
18 speed, or (d) vehicle heading not inbound.

APPENDIX B

Emergency Vehicle Traffic Signal Preemption System
Vehicle Transponder and Intersection Module Software:
Pseudo-code of Release Versions

```
//  
//  
//  
// The system allows emergency vehicles to preempt traffic intersections  
// and also provides visual indication (an LED sign) to motorists of  
// approaching emergency vehicles. The system is based on a short-range,  
// mobile wireless network with continuous reporting of vehicle state to  
// nearby intersections. The software is written in "C" for the ZWorld  
// LP3100 micro-controller.  
//  
// VEHICLE CONFIGURATION:  
//  
// This is the vehicle software component of the EViews Emergency  
Vehicle  
// Preemption System. It determines an emergency vehicle's location and  
// speed, identifies the state of the emergency vehicle (i.e. Code-3),  
// and transmits this information to a network of intersections. It  
also  
// provides feedback to the driver: (1) visual indication of whether the  
// vehicle is currently preempting an intersection, and (2) area mapping  
// data of other nearby emergency vehicles that are in Code-3.  
//  
// INTERSECTION CONFIGURATION:  
//  
// This is the intersection component of the EViews Emergency Vehicle  
// Preemption System. It monitors nearby vehicles in Code-3 and the  
// current timing of all traffic light phases and pedestrian clearance  
// phases. It uses these parameters to determine when to disable the  
// pedestrian crossing buttons and preempt the traffic signal. It also  
// broadcasts the current state of the intersection to the nearby Code-3  
// vehicles and other nearby intersections.  
//  
// MAJOR PARAMETERS USED INCLUDE:  
  
#define IS_TDMA 1 // is TDMA comm being used?  
#define MASTER_TXMT 1 // is the unit a master (repeater)?  
  
#define TYPE_VEH 0 // type of vehicle (fire, police, etc)
